CONCEPTUAL PAPER / PREPRINT DRAFT

Nash's Cage

Robust Viability-Constrained Payoff-Inversion Governance under Unknown Irreversible Boundaries

SpiralReality

Conceptual architecture with Ryō ∴ SpiralArchitect

Civilization is optimizing inside an unknown viability boundary.

Research revision v0.5

10 November 2026

This manuscript is a formal research proposal, not a claim of empirical validation or a finished institutional design.

Abstract

Climate governance is commonly framed as a cooperation problem in which individually rational actors underprovide a global public good. That framing is useful but incomplete. It does not, by itself, represent endogenous institutional delay, strategic metric manipulation, symbolic compliance, unequal externalization capacity, uncertain recovery boundaries, or the possibility that governance capacity deteriorates while physical risk accumulates. This paper introduces *Nash's Cage*: a partially observable, capture-prone stochastic dynamic game in which self-interested agents optimize short-horizon payoffs while externalizing physical and social constraints, thereby shrinking a robust viability region faster than institutions can observe, coordinate, and respond.

We formalize a companion architecture, the *Robust Viability-Constrained Cage-Inversion Model* (RVCIM). It combines heterogeneous utilities, manipulable observations, endogenous institutions, capture, model ambiguity, a robust viability kernel, and a braking-time measure termed *controllability reserve*. Its local propositions are conditional: monitoring cannot alter incentives through channels assumed absent; capture can offset nominal correction; non-positive reserve removes a timing certificate rather than proving realized failure; and a positive payoff differential makes cooperation strictly preferred among feasible alternatives, without ensuring joint execution. Viability and justice are proposed as constraints, not established by model performance.

This revision makes *joint executability* an explicit input contract: authority, actor-level cash and credit, shared resources, deadlines, continued service, and review must be compatible along the same non-anticipating protection pathway. It distinguishes physical scarcity, liquidity timing, uncertainty about others' performance, and incentive conflict. Existing synthetic failures and bounded public-data audits motivate these distinctions; they do not independently validate the resulting hypothesis. Prior work on coordination, liquidity, disaster finance, capabilities, and agenda setting already establishes much of this terrain. Our proposed contribution is a testable integration, not discovery of those mechanisms. A frozen finite timing assay now exposes target-completion gains that displace another service or fail to continue; its catalogue counts are not population frequencies. We further distinguish bearing a wait from being able to contest, revise, or leave its conditions. This is both a normative question and a separate, untested empirical candidate, not a conclusion from those synthetic outcomes. A second finite assay now reports a paid access package: on-time completion increases in 212 of 18,432 designed worlds, decreases in 6,370, and is unchanged in 11,850. The package charges a large setup cost and changes fee routing without retaining the old self-paid fallback; it is not a pure addition of rights. These internal results neither estimate real effects nor settle the normative value of contestation. The architecture remains F0, with no claim of empirical superiority, a universal Earth controller, or a restored pre-damage world.

Keywords: dynamic games; climate governance; viability theory; robust control; institutional capture; tipping points; deep uncertainty; control barrier functions; soundscape ecology; just transition.

Claim boundary

The term *Nash's Cage* does not imply that every Nash equilibrium is socially harmful, that climate politics reduces to a two-player Prisoner's Dilemma, or that automation can replace democratic judgment. It names a narrower model class: stable strategic configurations in which local best responses reproduce collective physical degradation and degrade the future capacity to change course.

Revision provenance

Revision v0.5, dated 10 November 2026, derives from repository v0.4 at commit `7ade9e01`. Sources, PDFs, and bibliographies for v0.1–v0.4 remain unchanged. Their historical provenance qualifications still apply. This revision incorporates the already completed waiting-contestability finite assay, including adverse results and limits of the implemented package. No new experiment is executed for this manuscript revision, and neither the frozen model nor its outcomes is changed. Both finite assays remain F0. Build checks, same-code replay, and independent output recount check different forms of consistency; none establishes empirical truth or independent authenticity.

1 Introduction

A Nash equilibrium is a profile from which no player benefits by unilateral deviation, given the strategies of the others (Nash, 1950). Stability in this sense is not equivalent to collective optimality. Common-pool resource problems, public-goods games, repeated dilemmas, and climate cooperation studies show that individually defensible choices can maintain collectively inferior outcomes (Hardin, 1968; Axelrod, 1984; Ostrom, 1990; Milinski et al., 2008; Nordhaus, 2015). Yet the climate problem is more difficult than the canonical matrix game: actors are heterogeneous, actions are continuous and path dependent, observations are delayed, institutional rules change endogenously, and some actors can spend resources to reshape the rules by which they are evaluated.

The empirical context motivates, but does not prove, the model. The Paris Agreement's Article 15 mechanism is expressly expert-based, facilitative, non-adversarial, and non-punitive (United Nations Framework Convention on Climate Change, 2015; United Nations Framework Convention on Climate Change, 2026). UNEP's 2025 assessment estimated end-of-century warming of roughly 2.3–2.5 °C under full implementation of current nationally determined contributions and 2.8 °C under current policies (United Nations Environment Programme, 2025). The 2025 Production Gap Report found that planned 2030 fossil-fuel production remained more than twice the level associated with a 1.5 °C pathway (Stockholm Environment Institute et al., 2025). The WMO reported a global mean atmospheric carbon dioxide concentration of 423.9 ppm in 2024 (World Meteorological Organization, 2025). These observations are consistent with a gap between symbolic commitment and physical trajectory, but they do not by themselves identify a single causal mechanism. RVCIMis proposed as a testable mechanism class.

Core claim

Diagnostic thesis. A candidate governance failure is weak, delayed, or manipulable coupling from observation to institutions, incentives, and physical response. But favorable incentives are insufficient if protection is not jointly executable. A protection pathway must first be distinguished from a promise, and an available pathway from one that actors will choose and sustain.

The paper develops six components of a research architecture, without claiming priority for their constituent theories.

1. It defines Nash's Cage as a partially observable, institutionally endogenous dynamic game rather than a static metaphor.

2. It distinguishes physical safety, robust viability, and operational braking reserve, allowing a state to appear safe while already lacking a certified path to stop.

3. It defines *payoff coupling strength*, linking KPI changes to the utility difference between cooperation and defection.

4. It models regulatory capture as an adversarial action vector that attacks sensors, models, actuators, delay, narratives, finance, and justice.

5. It specifies RVCIM, in which viability and justice are hard constraints, automatic triggers are accountable rather than discretionary, and policy pathways remain adaptive under deep uncertainty.

6. It makes joint execution, displaced burdens, and revisability explicit in an auditable pathway contract, and separates prospective mechanism tests from the exploratory evidence that suggested them.

2 Foundations and Scope

2.1 From bad equilibrium to a dynamic cage

The Prisoner's Dilemma is a useful local motif: if temptation exceeds mutual cooperation, mutual defection, and unilateral cooperation in the familiar ordering, defection is individually dominant while mutual cooperation is Pareto superior. Climate interactions, however, can also resemble assurance games, chicken, repeated public-goods games, bargaining games, common-pool resource games, and coalition games. Accordingly, Nash's Cage does not assert one universal payoff matrix. It asserts a dynamic property: for a decisive set of actors, the locally preferred actions reproduce degradation and resist unilateral exit.

Repeated interaction can sustain cooperation when future consequences, reputation, reciprocity, and credible punishment matter (Axelrod, 1984; Ostrom, 1990). Climate governance often weakens this "shadow of the future" through election cycles, quarterly reporting, capital turnover, jurisdictional leakage, and non-binding commitments. Climate clubs and coordinated trade measures have therefore been proposed as methods for changing free-riding incentives (Nordhaus, 2015). RVCIMgeneralizes the same intuition: the object of design is not moral exhortation but the intertemporal payoff field.

2.2 Partial observability and endogenous institutions

Dynamic noncooperative games explicitly represent evolving states and strategic feedback (Başar and Olsder, 1999). Partially observable decision processes distinguish the true state from the information available to the decision-maker (Kaelbling et al., 1998). In planetary governance, this distinction is essential: no actor observes the complete Earth-system state, the full distribution of future thresholds, or the true degree of institutional fragility. Moreover, the observation process is not neutral. Reporting boundaries, measurement choices, lobbying, accounting rules, and narrative framing can be strategic actions.

Institutions are therefore modeled as endogenous state variables and actuators, not fixed constraints. Regulatory capture research emphasizes that regulated interests can influence agencies, information, standards, and enforcement (Carpenter and Moss, 2014). Greenwashing research similarly treats symbolic environmental communication as an organizational response shaped by incentives and monitoring conditions (Delmas and Burbano, 2011). In the present model, symbolic action and capture are explicit elements of the action space.

2.3 Viability, safety, and deep uncertainty

Viability theory studies whether a controlled dynamical system can remain within a constraint set over time (Aubin et al., 2011). Control barrier functions encode safety conditions that can be enforced while pursuing performance objectives (Ames et al., 2017; Ames et al., 2019). Robust and adaptive decision frameworks address uncertainty in models, distributions, and future conditions; dynamic adaptive policy pathways emphasize sequencing, signposts, and switching rules rather than commitment to a single forecast (Haasnoot et al., 2013; Kwakkel et al., 2016).

The analogy to social governance must be used carefully. Institutions are not deterministic motors, citizens are not control inputs, and political legitimacy cannot be reduced to a quadratic program. The transfer is structural: safety should constrain optimization; uncertain boundaries require robustness; delay belongs inside the model; and a system should preserve the option to change course.

2.4 Earth-system boundaries and irreversible risk

Earth-system and planetary-boundary research identifies interacting biophysical processes that delimit a safe operating space (Rockström et al., 2023; Richardson et al., 2023). Climate tipping elements may exhibit threshold behavior, self-amplifying change, and hysteresis (Scheffer et al., 2009; Armstrong McKay et al., 2022). The IPCC assesses increasingly severe, interconnected, and in some cases irreversible risks with additional warming (Intergovernmental Panel on Climate Change, 2022; Intergovernmental Panel

on Climate Change, 2023). These literatures do not provide a single exact global cliff. They instead motivate the central uncertainty of this paper: the shape and distance of the true recovery boundary are only partially known.

UNEP's September 2026 *Limiting Overshoot* assessment states that exceedance of 1.5 °C is now expected, and that its magnitude and duration must be minimized while pursuing a return (United Nations Environment Programme, 2026). This is not reduced here to an isolated annual temperature anomaly. Nor does a return of global temperature restore lost lives, ecosystems, livelihoods, or institutions. For this architecture, a release rule must therefore distinguish ending an emergency power from ending continuing protection, compensation, and repair. A temperature target is not a sufficient statistic for the state left by its trajectory.

2.5 Prior contributions and the remaining research question

Coordination failure is not introduced by this paper. Cooper and John (1988) analyze strategic complementarities and inefficient equilibria; a feasible combination need not be the selected outcome. Holmström and Tirole (1998) distinguish private and public liquidity provision under different liquidity shocks. Their conditional theory does not make public funding unlimited, or turn finance into physical capacity. Morris and Shin (2002) show why information can affect strategic coordination, rather than only improve measurement. Neither a delay nor an information intervention identifies one of these mechanisms on its own.

Disaster-finance practice already combines financial timing with institutional execution. Ghesquiere and Mahul (2010) discuss administrative and legal readiness, budget transfers, coordination, procurement, and audit alongside liquidity and risk financing. Polycentric governance (Ostrom, 2010), administrative burden (Moynihan et al., 2015), adaptive pathways (Haasnoot et al., 2013), and constrained predictive control (Mayne et al., 2000) also precede the present synthesis. Their contributions constrain novelty claims: neither institutional plurality, transaction costs, sequencing, nor keeping future options open is new here. Engineering guarantees do not transfer to social institutions merely because similar notation is used.

Sen (1980) distinguishes resources and utility from what a person is able to do. We use that distinction to ask whether protection is actually usable, not to derive a universal capability score. Bachrach and Baratz (1962) and Bachrach and Baratz (1963) make agenda boundaries and nondecisions objects of inquiry. Debnam (1975) challenges the conceptual distinctions and empirical utility of that framework. We retain this criticism: non-application, exclusion, silence, and missing records are not by themselves evidence of intentional suppression.

The contribution proposed here is a domain-bounded, auditable contract linking recipient-level protection to actor-specific commitments, financial timing, shared capacity, alternative routes, continuation, and correction. Its value must be tested against simpler existing arrangements. The repository catalogue records the contribution, limitations, and actual reading scope of each source; this is a selective synthesis, not a systematic review, a priority claim, or a replication of the cited studies.

3 Model Primitives

3.1 State, agents, and action space

Let time be discrete, $t = 0, 1, \ldots$, and let $\mathcal{N} = \{1, \ldots, N\}$ denote heterogeneous actors. An actor may represent a state, firm, financial institution, regulator, local government, sectoral coalition, or organized public. The full state is

$$\boldsymbol{x}_t = (\boldsymbol{s}_t, \boldsymbol{z}_t, \boldsymbol{\iota}_t, \boldsymbol{n}_t), \tag{3.1}$$

where $\boldsymbol{s}_t$ is the physical state, $\boldsymbol{z}_t$ contains actor-specific stocks and dependencies, $\boldsymbol{\iota}_t$ is the institutional state, and $\boldsymbol{n}_t$ is the cognitive and legitimacy state.

Table 1: Layered state representation. The variables are illustrative rather than exhaustive.

Layer	Representative variables	Interpretation
Physical	C_t, B_t, X_t, L_t, W_t	Atmospheric forcing; biosphere integrity; tail-event intensity; infrastructure stress; water, food, and coupled life-support states.
Agent	$E_{i,t}, F_{i,t}, D_{i,t}, G_{i,t}$	Emissions; fossil dependence or production; direct decarbonization; symbolic compliance.
Institution	$P_t, Q_t, M_t, \tau_t, J_t$	Penalty strength; transition support; monitoring fidelity; policy delay; justice and compensation capacity.
Cognition	$\Phi_t, A_t^{\text{ware}}, T_t^{\text{rust}}$	Dominant narrative frame; public awareness; trust and legitimacy.
Irreversibility	$\mathcal{V}_t, CR_t, \rho_t$	Viability region; controllability reserve; robust recovery probability.

Actor i chooses

$$\boldsymbol{a}_{i,t} = (e_{i,t}, f_{i,t}, d_{i,t}, g_{i,t}, \ell_{i,t}, r_{i,t}, h_{i,t}), \tag{3.2}$$

where the components denote emissions, fossil production or dependence, direct decarbonization, symbolic action, capture or delay effort, ecological restoration, and adaptation. Including $g_{i,t}$ and $\ell_{i,t}$ is essential: a model that treats performative compliance and rule-shaping as exogenous noise omits strategies that may be cheaper than physical transformation.

The physical dynamics are

$$\boldsymbol{s}_{t+1} = F_\theta(\boldsymbol{s}_t, \boldsymbol{a}_t, \boldsymbol{\xi}_t), \qquad \theta \in \Theta_t, \tag{3.3}$$

with aggregate action $\boldsymbol{a}_t = (\boldsymbol{a}_{1,t}, \ldots, \boldsymbol{a}_{N,t})$, disturbance $\boldsymbol{\xi}_t$, and model index θ. Illustrative components are

$$C_{t+1} = C_t + \sum_i e_{i,t} - \text{Sink}_\theta(B_t, C_t, \text{heat}, \text{drought}, \text{fire}), \tag{3.4}$$

$$B_{t+1} = B_t - \alpha C_t - \beta U_t^{\text{land}} - \gamma U_t^{\text{pollution}} - \delta U_t^{\text{noise/light}} + \sum_i r_{i,t}. \tag{3.5}$$

The sink is endogenous: degradation can reduce future absorptive capacity. Tail risk is represented as

$$q_{j,t}^{\text{tail}} = \mathbb{P}_\theta\Big(X_{j,t} > \Theta_j^{\text{design}} \mid \boldsymbol{s}_t\Big), \tag{3.6}$$

not merely by a change in the mean. Cascades may be modeled through an interdependency graph among power, water, food, health, logistics, communications, finance, and governance.

3.2 Utility, horizons, and externalization

Let Π_i^{feas} denote actor i's feasible policies. A generic discounted objective is

$$U_i(\pi_i, \pi_{-i}; \theta) = \mathbb{E}_\theta \sum_{k=0}^{H_i} \beta_i^k \Big[G_i^{\text{econ}}(e_i, f_i) + B_i^{\text{free}}(a_{-i}) + B_i^{\text{sym}}(g_i, n) + Q_i(d_i, r_i; \iota, k) - C_i^{\text{trans}}(d_i, r_i, h_i) - P_i(e_i, f_i; \iota, k) - D_i(s) - C_i^{\text{audit}}(g_i, \ell_i; M) - C_i^{\text{legal}}(a_i; \iota) - C_i^{\text{cap}}(\ell_i) \Big]. \tag{3.7}$$

Short political and financial horizons are represented by small H_i or low β_i. Climate damage borne by the actor is

$$D_i(s_t) = E_i^{\text{exposure}} V_i^{\text{vulnerability}} \eta_i^{\text{internalization}} D(s_t), \qquad \chi_i^{\text{externalization}} = 1 - \eta_i^{\text{internalization}}. \tag{3.8}$$

Powerful actors may lower $\eta_i^{\text{internalization}}$ through insurance, relocation, price pass-through, legal privilege, supply-chain displacement, or temporal deferral. Benefits are internalized; losses are displaced across jurisdiction, class, species, or generation.

3.3 Observation, KPI construction, and manipulation

The true state is not directly observed. Raw observations satisfy

$$y_t = O_\theta(x_t, a_t) + \varepsilon_t + \mu_t, \tag{3.9}$$

where ε_t is measurement and model error and μ_t is strategic manipulation. The institutional KPI vector is produced by a fusion operator

$$k_t = \mathcal{H}(y_{0:t}; \mathcal{M}_t), \tag{3.10}$$

where $\mathcal{M}_t$ contains models, baselines, accounting rules, and metadata. A stylized integrity score is

$$\mathsf{DI}_t = \frac{M_t^{\text{fidelity}} M_t^{\text{independence}} M_t^{\text{comparability}}}{1 + O_t^{\text{opacity}} + U_t^{\text{manipulability}} + F_t^{\text{political}}}. \tag{3.11}$$

More data do not necessarily imply more truth. A sufficiently opaque or incomparable reporting regime can increase audit cost while preserving strategic ambiguity.

3.4 Institutional and narrative dynamics

Let Γ map KPI deviations into pre-legislated adjustments to taxes, subsidies, supply caps, permits, trade rules, public finance, restoration, and compensation. Institutional dynamics are

$$\iota_{t+1} = \text{Proj}_{\mathfrak{I}} \left[\iota_t + \Gamma(k_t - \bar{k}_t) - c_t - \varphi_t \right], \tag{3.12}$$

where c_t is strategic capture and φ_t is ordinary friction or capacity loss. Capture is decomposed as

$$c_t = (c_t^K, c_t^I, c_t^\tau, c_t^N, c_t^J, c_t^F), \tag{3.13}$$

attacking the sensor/KPI layer, institutional actuator, response time, narrative, justice reserve, and financial transmission.

Narratives evolve according to

$$n_{t+1} = \Psi(n_t, k_t, \text{events}_t, \text{media}_t, \text{interests}_t, \text{lived impacts}_t). \tag{3.14}$$

Actors optimize against perceived states

$$\widetilde{\boldsymbol{x}}_{i,t} = \mathcal{P}_i(\boldsymbol{y}_{0:t}, \boldsymbol{k}_t, \boldsymbol{n}_t, \text{interests}_i), \qquad \boldsymbol{a}_{i,t} \in \arg\max_{\boldsymbol{a}_i} U_i(\boldsymbol{a}_i \mid \widetilde{\boldsymbol{x}}_{i,t}, \boldsymbol{\iota}_t). \tag{3.15}$$

Physical reality is therefore mediated by observation and meaning before it becomes action.

4 Nash's Cage: Definition and Local Results

4.1 Cooperation, defection, and decisive actors

For a specified governance problem, partition feasible policies into cooperative and defective sets, Π_i^C and Π_i^D. The partition is empirical and context-dependent: direct verified emissions reduction may be cooperative, while boundary laundering may be defective even when legally compliant. Define

$$\Delta_i(\boldsymbol{x}_t) = \sup_{\boldsymbol{\pi}_i \in \Pi_i^C} U_i(\boldsymbol{\pi}_i, \boldsymbol{\pi}_{-i}) - \sup_{\boldsymbol{\pi}_i \in \Pi_i^D} U_i(\boldsymbol{\pi}_i, \boldsymbol{\pi}_{-i}). \tag{4.1}$$

Thus $\Delta_i < 0$ means that defection is preferred. A set $\mathcal{D} \subseteq \mathcal{N}$ is *decisive* if its joint control over emissions, production, finance, technology, enforcement, or demand exceeds a problem-specific critical weight.

Orient KPI components so that positive deviations represent worsening conditions, and let $\boldsymbol{d}_t \in \mathbb{R}_+^m$ be a normalized policy-relevant deterioration direction. The directional coupling from observation to incentives is

$$\Lambda_i(t; \boldsymbol{d}_t) = D_{\boldsymbol{d}_t} \Delta_i = (\nabla_{\boldsymbol{k}} \Delta_i)^\top \boldsymbol{d}_t \tag{4.2}$$

$$= (\nabla_{\boldsymbol{\iota}} \Delta_i)^\top \frac{\partial \boldsymbol{\iota}}{\partial \boldsymbol{k}} \boldsymbol{d}_t + (\nabla_{\boldsymbol{n}} \Delta_i)^\top \frac{\partial \boldsymbol{n}}{\partial \boldsymbol{k}} \boldsymbol{d}_t. \tag{4.3}$$

The first term is formal policy transmission; the second captures reputational and legitimacy pathways. We write Λ_i when the direction is clear. An observation system with high fidelity but $\Lambda_i \approx 0$ can document failure without changing it.

Definition 4.1 (Nash's Cage)**.** Over a window $[t, t+H]$, a system is in a Nash's Cage with respect to a decisive set $\mathcal{D}$ when the following conditions jointly hold to a policy-relevant degree:

(C1) $\Delta_i < 0$ for all or a controlling share of $i \in \mathcal{D}$;

(C2) a robust viability margin is non-increasing or deteriorating;

(C3) payoff coupling Λ_i is weak, delayed, or strategically neutralized;

(C4) effective capture is at least as strong as the institutional correction it opposes; and

(C5) symbolic compliance grows faster than verified physical improvement.

A simple performative gap is

$$\mathsf{PG}_t = \|\boldsymbol{g}_t\| - \kappa \left\| \Delta \boldsymbol{s}_t^{\text{verified},+} \right\|, \tag{4.4}$$

where $\Delta \boldsymbol{s}^{\text{verified},+}$ denotes verified improvement in physical states and κ maps units. Its purpose is diagnostic, not moral: it asks whether communication and accounting are decoupling from physical response.

4.2 Conditional propositions

Proposition 4.2 (Performative monitoring)**.** *Suppose, locally, that Δ_i depends on the KPI only through institutional and narrative channels, all maps are differentiable, and*

$$\frac{\partial \boldsymbol{\iota}}{\partial \boldsymbol{k}} = 0, \qquad \frac{\partial \boldsymbol{n}}{\partial \boldsymbol{k}} = 0.$$

Then $\Lambda_i(t; \boldsymbol{d}) = 0$ for every direction $\boldsymbol{d}$. Increasing observation fidelity alone cannot locally change the actor's cooperation–defection payoff differential.

Proof. Apply the chain rule to Equation (4.3). Both transmission terms vanish. The conclusion is local and conditional; new information may still matter if it changes beliefs, narratives, litigation, or institutional design through a path excluded by the assumptions. □

Proposition 4.3 (Capture dominance)**.** *Let $\boldsymbol{v}$ be an enforcement direction in institutional state space. If*

$$\left\langle \boldsymbol{v}, \Gamma(\boldsymbol{k}_t - \bar{\boldsymbol{k}}_t) \right\rangle \leq \langle \boldsymbol{v}, \boldsymbol{c}_t + \boldsymbol{\varphi}_t \rangle \,, \tag{4.5}$$

then the institutional update in that direction is non-positive before projection. A worsening KPI need not strengthen enforcement.

Proof. Take the inner product of Equation (3.12) before projection with $\boldsymbol{v}$. The net directional increment is the left-hand trigger minus capture and friction. Under Equation (4.5), it is non-positive. □

Proposition 4.4 (Payoff inversion)**.** *Fix the strategies of other actors and the institutional state. Suppose cooperative and defective feasible sets are nonempty and their utility maxima exist. If $\Delta_i > 0$ for each actor in a decisive coalition $\mathcal{D}$, cooperation is strictly preferred by those actors over the stated alternatives. At $\Delta_i = 0$, cooperation may also be chosen as a best response. Strict positivity is therefore sufficient for strict preference, not necessary for observed cooperation, and does not establish joint executability, equilibrium selection, or physical viability.*

Proof. Compare the two attained maxima in Equation (4.1). A positive difference strictly ranks the cooperative maximum above the defective one; equality permits a tie. The comparison holds others' strategies fixed. Their subsequent responses, incompatible shared-resource demands, physical lags, and model error can defeat joint execution or recovery even after these individual rankings change. □

5 Joint Executability of Protection

5.1 Four mechanisms, not one friction parameter

A favorable payoff comparison does not imply that an action can be financed, authorized, staffed, or completed in time. Conversely, resources and authority do not imply willingness to act. We distinguish four candidate explanations before examining an intervention's result.

Table 2: Mechanisms to distinguish prospectively. The rows can coexist; an unresolved mixture is not a diagnosis.

Mechanism	Missing condition	Discriminating evidence
Physical scarcity	Staff, equipment, energy, or service capacity, including substitutes.	A payment or promise alone cannot supply an absent input. Track shared capacity and displacement.
Liquidity timing	Spendable cash or usable credit at a required intermediate time.	Trace an early shortfall despite an eventual entitlement; measure both recipient and payer balances.
Performance uncertainty	A credible expectation that another required actor will perform.	A commitment change with funding and payoffs separately accounted for; otherwise a bundled effect remains unidentified.
Incentive conflict	Acting remains unattractive even if others perform.	A prespecified payoff change rather than reassurance alone; record actual feasible alternatives.

Legal authority, rights, and existing protection constrain every row. They are not residuals to be removed when a model fails. An actor may have an enforceable duty even when a proposed additional incentive is unattractive; the classification is explanatory, not permission to evade that duty.

5.2 A pathway-level input contract

Restrict a case to a declared place, service, and horizon. Describe each action by its responsible actor, authority and applicable rule version, prerequisites, start and completion clocks, payer, physical inputs, substitutes, and review or release conditions. Enrollment, authorization, payment, service delivery, protection, and continued protection are separate events. Contractual deadlines, operational review times, and physical or medical limits must also remain distinct. An unknown irreversible threshold cannot supply an invented safe waiting period.

Let $L_i(t)$ be actor i's available funds at the initial time and $\underline{L}_i(s)$ its declared protected minimum. Under policy π, institutional arrangement m, and scenario θ, intermediate financial slack is

$$\ell_i(s;\pi,m,\theta) = L_i(t) + \sum_{\tau=t}^{s} \mathrm{In}_i(\tau) - \sum_{\tau=t}^{s} \mathrm{Out}_i(\tau) - \underline{L}_i(s). \tag{5.1}$$

Approval is not cash. Include credit only where it is actually drawable, with repayment obligations, and do not count the same credit twice. Transfers between actors are not additive social resource costs at every intermediary. Protected minima and rights floors require a public justification; this equation does not choose them.

Let Π_{NA} contain policies using only each actor's available history, not future shocks or evaluator-only truth. Write the conceptual deadline-constrained execution set as

$$\mathcal{E}^{H}_{m}(t) = \left\{ \pi \in \Pi_{\mathrm{NA}} : \begin{array}{l} \text{for all } \theta \in \Theta \text{ and required times } s \in [t, t+H], \\ \text{authority, existing protection, and rights are respected;} \\ \ell_i(s;\pi,m,\theta) \geq 0 \text{ for each necessary actor;} \\ \text{shared-resource, capacity, and conservation constraints hold;} \\ \text{actions meet their declared deadlines, with required service,} \\ \text{continuation, reassessment, and transition conditions.} \end{array} \right\}. \tag{5.2}$$

The same non-anticipating policy must work across the declared ambiguity set. This is an input specifica-

tion, not a computed real-world robust certificate. A finite search finding no candidate does not establish that $\mathcal{E}_m^H(t)$ is empty; missing inputs imply *unconfirmed*, not impossible. Membership also does not establish the intervention's physical efficacy. Alternative routes may avoid particular intermediaries, so universal participation is not required.

5.3 Redistribution, opportunity costs, and a conditional prediction

Moving a transfer M from payer j to recipient i earlier changes their slack by $+M$ and $-M$ during the advanced interval, if all other flows are held fixed and there is no new credit, outside funding, or extra cost. The combined change is zero, but feasibility can improve if the payer can bear the interval and the recipient cannot. Burden transfer is therefore neither automatically failure nor proof of improvement. Inspect displaced protection, financing and administration costs, and sustainability at both ends. The criterion is not that nobody may bear any additional burden; redistribution and existing duties remain possible.

If an option is free, may be ignored, and leaves the objective, resources, rights, and other actors' responses unchanged, then $\mathcal{E}_0 \subseteq \mathcal{E}_1$ implies

$$\sup_{\pi \in \mathcal{E}_1} V(\pi) \geq \sup_{\pi \in \mathcal{E}_0} V(\pi). \tag{5.3}$$

This elementary set-inclusion result is not a new theorem. A paid linkage scheme, constrained budget, or fixed decision rule need not satisfy its premises. For example, with divisible homogeneous service, ample demand, budget B, unit cost c, capacity K, setup cost $0 \leq F < B$, and on-time delivery fractions q_0, q_1, a one-period reduction gives

$$A_0 = q_0 \min\{K, B/c\}, \qquad A_1 = q_1 \min\{K, (B-F)/c\}. \tag{5.4}$$

If both arms are budget-bound and $q_0 > 0$, $A_1 > A_0$ exactly when $q_1/q_0 > B/(B-F)$. For $q_0 = 0$, use the original difference, not a ratio. This is delivered service, not a clinical benefit estimate, and omits heterogeneity, credit, repeated use, and maintenance. It explains why paid coordination need not dominate direct provision; it does not establish a real coefficient.

Hypothesis 5.1 (Joint executability: prospective timing comparison)**.** With existing protection retained, moving an equal nominal transfer before required expenditure increases the rate of completing a declared protective service by its operational deadline in a prespecified liquidity-constrained group C, provided necessary authority, physical inputs, and time are available and the payer can sustain the advance. Let Δ_g be the early-minus-late effect on that rate in pre-intervention group g, and let U be a group without the intermediate shortfall. Test separately $\Delta_C > \delta_C$ and $\Delta_C - \Delta_U > \delta_I$, for positive meaningful margins fixed before outcomes. The relative contrast alone is insufficient: both groups could worsen. Setup and financing costs, shared-capacity displacement, continued service, and actual protection outcomes are additional separately reported outcomes, not erased by a favorable execution-rate result.

This prediction is suggested by the earlier development work, not confirmed by it. A precise null or contrary interaction would count against this specified prediction. An imprecise estimate is unresolved, not supporting evidence. Credit, in-kind provision, permanent services, and independent rescue routes may already remove the shortfall. Equal nominal transfers are not equal total intervention costs; any fixed-resource policy comparison must separately specify whose envelope is held equal and how extra costs reduce other uses.

5.4 Separate candidate: losing a feasible path while waiting

A further candidate is that an initially executable pathway disappears while actors wait for a credible commitment or a prespecified incentive change. To test it, establish initial feasibility, record who waits for whose action, identify the capacity or time lost during that interval, and distinguish external dete-

rioration from waiting-related loss. A credible commitment without behavioral change is adverse to the performance-uncertainty branch but can be consistent with incentive conflict. The latter requires its own prespecified payoff contrast. Guarantees that also unlock credit do not isolate beliefs from liquidity. Mixed mechanisms remain unidentified unless the design separates them. This candidate must not be added after a failed timing test as an unfalsifiable rescue explanation.

6 Unknown Irreversible Boundaries

6.1 Safety is not viability

Let $\mathcal{X}_{\text{safe}} \subseteq \mathcal{X}$ be a constraint set: states that satisfy specified physical, social, and justice conditions at the present time. For a known model θ, the viability kernel is

$$\mathcal{V}_\theta = \left\{ \boldsymbol{x}_0 \in \mathcal{X}_{\text{safe}} : \exists \boldsymbol{\pi} \in \Pi^{\text{feas}} \text{ such that } \boldsymbol{x}_t \in \mathcal{X}_{\text{safe}} \ \forall t \geq 0 \right\}. \tag{6.1}$$

A state can lie in $\mathcal{X}_{\text{safe}}$ yet outside $\mathcal{V}_\theta$: current conditions have not violated the constraint, but no feasible future policy can prevent eventual exit. This distinction replaces the image of one visible "point of no return" with a control-dependent boundary.

The true model is unknown. Let Θ_t be an ambiguity set containing plausible physical, technological, economic, and institutional dynamics, plus an explicit structural-error allowance. For a measurable set $\mathcal{A}$, define the first-passage delay from decision time t by

$$\tau_{\mathcal{A}}^{(t)} = \inf\{h \in \mathbb{N}_0 : \boldsymbol{x}_{t+h} \in \mathcal{A}\}, \qquad \inf \varnothing = +\infty. \tag{6.2}$$

Define the robust viability set over horizon H as

$$\mathcal{V}_t^{\text{rob}} = \left\{ \boldsymbol{x}_t \in \mathcal{X}_{\text{safe}} : \exists \boldsymbol{\pi} \in \Pi^{\text{feas}} \text{ such that } \sup_{\theta \in \Theta_t} \mathbb{P}_\theta \left(\min\{\tau_{\mathcal{X}_{\text{safe}}^c}^{(t)}, \tau_{\mathcal{X}_{\text{irr}}}^{(t)}\} \leq H \mid \boldsymbol{x}_t, \boldsymbol{\pi} \right) \leq \varepsilon \right\}. \tag{6.3}$$

The same admissible policy must keep the probability of leaving the safe set or entering a policy-defined functionally irreversible region below the risk tolerance across the ambiguity set.

6.2 Functional irreversibility

Irreversibility is separated into four classes:

1. **Physical**: recovery is impossible on human policy timescales.
2. **Hysteretic**: the return threshold differs from the collapse threshold.
3. **Practical**: recovery is physically possible but exceeds feasible time, energy, finance, or infrastructure.
4. **Institutional**: recovery is physically possible but governance, trust, coordination, or legal capacity is insufficient.

Thus

$$\mathcal{X}_{\text{irr}} = \mathcal{X}_{\text{phys}} \cup \mathcal{X}_{\text{hyst}} \cup \mathcal{X}_{\text{practical}} \cup \mathcal{X}_{\text{institutional}}. \tag{6.4}$$

A robust recovery score is

$$\rho_t(H) = \sup_{\boldsymbol{\pi} \in \Pi^{\text{feas}}} \inf_{\theta \in \Theta_t} \mathbb{P}_\theta \left(\boldsymbol{x}_{t+H} \in \mathcal{X}_{\text{safe}}, \tau_{\mathcal{X}_{\text{irr}}}^{(t)} > H \mid \boldsymbol{x}_t, \boldsymbol{\pi} \right). \tag{6.5}$$

If $\rho_t(H) < \rho_{\min}$, the system is functionally irreversible relative to the chosen horizon, capabilities, ambi-

guity set, and safety definition. This is not a metaphysical claim that no future civilization could reverse the state; it is an operational statement about feasible control now.

6.3 Controllability reserve

The critical event may occur before a visible boundary is crossed: the system loses enough time that even a correct response cannot take effect before exit. Let

$$T^{L}_{\text{exit}}(t) = \inf_{\theta \in \Theta_t} Q^{\theta}_{q_L}\left[\tau^{(t)}_{\mathcal{X}_{\text{irr}}} \mid \boldsymbol{x}_t\right] \tag{6.6}$$

and

$$T^{U}_{\text{response}}(t) = \sup_{\theta \in \Theta_t} Q^{\theta}_{q_U}\big[T_{\text{detect}} + T_{\text{verify}} + T_{\text{political}} + T_{\text{legal}} + T_{\text{finance}} + T_{\text{infrastructure}} + T_{\text{biophysical}}\big]. \tag{6.7}$$

The controllability reserve is

$$\boxed{CR_t = T^{L}_{\text{exit}}(t) - T^{U}_{\text{response}}(t).} \tag{6.8}$$

The quantiles q_L and q_U encode a chosen risk posture; they are not universal constants.

Proposition 6.1 (Delay-induced loss of certified braking capacity)**.** *If $CR_t \le 0$ and no admissible faster response lies outside the modeled response set, then the system lacks a robust certificate that intervention can take effect before entry into $\mathcal{X}_{\text{irr}}$. Under a separately declared precautionary decision rule, this condition triggers precautionary or emergency escalation even if the observed state remains inside $\mathcal{X}_{\text{safe}}$.*

Proof. By Equation (6.8), the conservative time to exit is no greater than the conservative response time. Therefore the model cannot certify that the response completes first. The timing result establishes loss of certification; escalation follows from the declared precautionary rule, not from the inequality alone. Neither establishes that irreversible entry will occur in the realized world. □

Reserve is multidimensional. Let normalized components represent physical, observability, actuation, coordination, and justice/legitimacy capacity:

$$CR^{\text{sys}}_t = \min\{\widetilde{R}^{P}_t, \widetilde{R}^{O}_t, \widetilde{R}^{A}_t, \widetilde{R}^{C}_t, \widetilde{R}^{J}_t\}. \tag{6.9}$$

The minimum, rather than an average, reflects a bottleneck claim: excellent sensing does not compensate for absent enforcement; strong enforcement does not compensate for zero legitimacy; legitimacy does not restore an already exhausted physical reserve.

6.4 Endogenous optimism and doom

Civil systems often behave as if $\rho_t > 0$ because finance, investment, insurance, electoral legitimacy, and consumption depend on an operative future. Let an optimism distortion satisfy

$$\widehat{\rho}_t = \rho_t + o_t + \epsilon^{\rho}_t, \tag{6.10}$$

where o_t may be psychological, institutional, or strategic. Optimism is not the only dangerous distortion. Certainty of doom can shorten horizons, reduce cooperation, and produce disengagement. RVCIMtherefore adopts neither "recovery is assured" nor "collapse is certain." It treats uncertainty about high-consequence irreversibility as a reason to preserve options and braking capacity.

7 The RVCIM Governance Architecture

7.1 Viability and justice as hard constraints

A conventional weighted welfare objective can make an irreplaceable loss appear compensable by sufficiently large economic benefit. RVCIMinstead uses constrained or lexicographic optimization:

$$\boldsymbol{\pi}^\star = \operatorname{lexmin}_{\boldsymbol{\pi}} \left(\mathcal{R}_{\text{irr}}(\boldsymbol{\pi}), \mathcal{R}_{\text{justice}}(\boldsymbol{\pi}), -\mathcal{W}_{\text{durable}}(\boldsymbol{\pi}) \right), \tag{7.1}$$

or, in a thresholded implementation,

$$\max_{\boldsymbol{\pi} \in \Pi^{\text{feas}}} \quad \mathcal{W}_{\text{durable}}(\boldsymbol{\pi}) \tag{7.2}$$

$$\text{subject to} \quad \sup_{\theta \in \Theta_t} \mathbb{P}_\theta(\tau^{(t)}_{\mathcal{X}_{\text{irr}}} \le H \mid \boldsymbol{\pi}) \le \varepsilon, \tag{7.3}$$

$$R_t^J \ge J_{\min}, \tag{7.4}$$

$$\mathcal{L}_{\text{nonfungible}}(\boldsymbol{\pi}) = 0. \tag{7.5}$$

Species extinction, destruction of irreplaceable ecosystems, or intolerable distributional harm are not assumed tradable against aggregate income.

7.2 Robust barrier conditions

Let $h_{j,\theta}(\boldsymbol{x}) \ge 0$ encode safety condition j under model θ. A governance action is admissible only if

$$\sup_{\theta \in \Theta_t} \mathbb{P}_\theta \left[\min_j h_{j,\theta}(\boldsymbol{x}_{t+1}) < 0 \mid \boldsymbol{x}_t, \boldsymbol{\iota}_t \right] \le \varepsilon_t. \tag{7.6}$$

A stronger margin-preservation condition is

$$\inf_{\theta \in \Theta_t} \min_j h_{j,\theta}(\boldsymbol{x}_{t+1}) \ge (1 - \kappa_t) \inf_{\theta \in \Theta_t} \min_j h_{j,\theta}(\boldsymbol{x}_t). \tag{7.7}$$

These equations are institutional design analogies to robust safety control, not claims that democratic governance admits exact barrier certificates.

7.3 Payoff inversion controller

The controller must change the utility differential, not merely issue a signal. The relevant chain is

$$\boldsymbol{k}_t \longrightarrow \boldsymbol{\iota}_{t+1} \longrightarrow \Delta_i(t+1) \longrightarrow \boldsymbol{a}_{i,t+1} \longrightarrow \boldsymbol{s}_{t+2}. \tag{7.8}$$

A sufficient local design target for the decisive coalition is

$$\begin{aligned} \Delta_i = {} & \underbrace{B_i^{\text{transition}} + B_i^{\text{market}} + B_i^{\text{legitimacy}}}_{\text{cooperation gains}} + \underbrace{C_i^{\text{avoided penalty}}}_{\text{credible enforcement}} \\ & - \underbrace{C_i^{\text{transition}}}_{\text{conversion burden}} - \underbrace{B_i^{\text{fossil}} + B_i^{\text{free}} + B_i^{\text{greenwash}} + B_i^{\text{delay}}}_{\text{defection gains}} > 0. \end{aligned} \tag{7.9}$$

The design must both raise the expected cost of defection and lower the feasible cost of cooperation. Penalty without transition support creates backlash; subsidy without enforcement preserves free-riding.

7.4 Trigger modes

Table 3: Reserve-based control modes. Thresholds must be domain-specific and pre-legislated.

Mode	Entry condition	Illustrative response
0: Adaptive normal	$\underline{CR}_t > m_1$	Monitoring, low-regret investment, adaptive pathway maintenance, routine redistribution.
1: Precaution	$0 < \underline{CR}_t \le m_1$ or boundary uncertainty above tolerance	Stronger carbon and methane controls, tighter supply caps, higher audit frequency, stricter proof burden for one-way actions.
2: Emergency braking	$\underline{CR}_t \le 0$ or high probability of near-term negative reserve	Temporary moratoria on new irreversible commitments, accelerated demand reduction, finance reallocation, rapid transition and justice buffers.
3: Loss minimization	$\rho_t(H) < \rho_{\min}$	Protect life-support systems, relocation, compensation, biodiversity refugia, cultural preservation, and safeguarding of still-viable subsystems.

Every trigger requires a release rule. Otherwise emergency governance can itself be captured and made permanent.

7.5 One-way doors and burden of proof

For normalized factors $I, S, D, U \in [0, 1]$ representing irreversibility, scale, duration, and uncertainty, define a One-Way Door index

$$\mathsf{OWD}(a) = I(a)\, S(a)\, D(a)\, U(a), \tag{7.10}$$

As OWD rises, the acceptable risk $\varepsilon(a)$ falls. High-OWD actions are permitted only when the proponent demonstrates robust safety relative to the status quo:

$$\sup_{\theta \in \Theta_t} \mathbb{P}_\theta(\tau^{(t)}_{\mathcal{X}_{\text{irr}}} \le H \mid a) \le \varepsilon(a), \qquad \varepsilon'(\mathsf{OWD}) < 0. \tag{7.11}$$

The status quo is not a zero-risk baseline. A new action may be precautionary when inaction has higher irreversible risk.

7.6 Accountable automation and institutional separation

Automation here means rule-bound transmission, not removal of politics. The policy rule is democratically authorized in advance; implementation becomes less discretionary after the trigger fires. An override is admissible only with

$$\mathsf{Override} = \mathsf{PublicReason} + \mathsf{Expiry} + \mathsf{IndependentReview} + \mathsf{Compensation} + \mathsf{AuditTrail}. \tag{7.12}$$

Appeal must not create free delay; disputed liabilities can be placed in escrow.

The architecture separates six functions:

$$\boxed{\mathsf{Sensor} \neq \mathsf{Modeler} \neq \mathsf{Trigger} \neq \mathsf{JusticeAllocator} \neq \mathsf{Auditor} \neq \mathsf{Appeal}.} \tag{7.13}$$

No single actor should control measurement, model selection, KPI computation, enforcement, audit, and exception review.

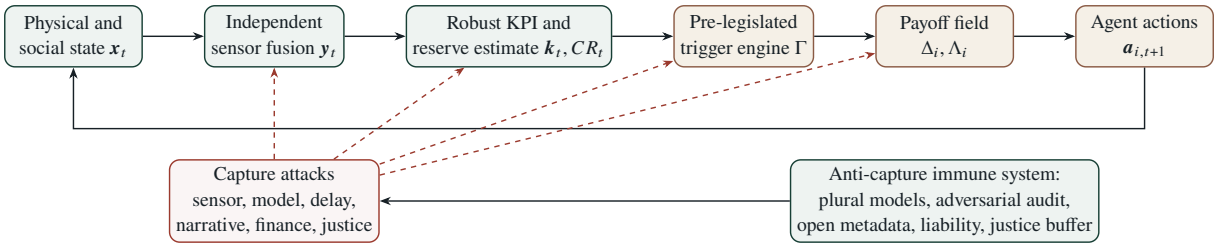

Figure 1: Closed-loop architecture. The red dashed paths represent strategic attacks; the lower control path represents anti-capture defenses.

8 Protection, Selection Boundaries, and Revisability

Existing institutions must remain in the baseline, including ordinary social insurance, direct protective duties, and alternative routes. But respecting an institution as an observed variable does not make its budget or eligibility boundary normatively final. A fixed-budget comparison identifies a bounded decision problem; it does not justify that budget allocation. The distinctions in Section 2.5 motivate recording proposals, agenda access, eligibility, non-application, rejection, appeals, and rule changes without inferring either consent or oppression from silence.

Building on the resource–capability distinction, we make a separate *normative proposal*: protection should be evaluated alongside the recipient's ability to question its conditions and seek correction. This is not unconditional maximization of choices, permission to harm others' life-support conditions, a discretionary veto over existing protective duties, or a reduction of ecological value to human capability. Nor can a statistical result settle the legitimacy of an allocation.

The corresponding *empirical candidate* is narrower: an accessible route from contestation to independent reassessment and correction may reduce persistent exclusion or erroneous intervention. Evaluate access costs, retaliation concerns, processing time, unresolved cases, protection outcomes, and the burden on other services. Appeal counts alone are ambiguous: more claims may reflect more harm or improved access; few claims need not mean few problems. The relevant denominator extends beyond accepted applicants, and some excluded needs may remain unobserved.

Immediate rescue must not wait for a completed research audit or unanimous agreement. Independent review, correction, compensation, and release of exceptional powers must coexist with timely protection. These safeguards already appear in earlier RVCIM drafts. This revision makes their recipient-level observation requirements explicit rather than claiming to invent appeal or anti-capture governance.

8.1 Who can change the conditions of waiting?

The ability to finance a wait is not the ability to refuse or revise its terms. A recipient may possess bridge funding yet lose access to promised protection by pursuing an alternative, challenging a condition, or leaving an exclusive pathway. Conversely, an authorized pause can enable safety checks, informed choice, and fair allocation. Delay alone identifies neither coercion nor institutional failure. This extension operationalizes the existing capability, administrative-burden, and agenda-setting concerns in Section 2.5; it does not introduce those concerns as new discoveries.

For each declared service and affected actor, record who may initiate, extend, and end a suspension; its stated grounds and review date; available reassessment and substitute routes; the information, money, and time needed to use them; and any change in eligibility or continuing support after their use. Distinguish a route named in a rule from one that can be exercised before the relevant deadline. Unknown access conditions remain unknown, not zero. A broad right to appeal is not an automatic right to a favorable decision, unlimited resources, or priority over another person's necessary protection.

Write a descriptive, actor-specific record

$$\mathcal{W}_i(t) = \big(D_i(t),\ A_i(t),\ C_i(t),\ P_i(t),\ O_i(t)\big), \tag{8.1}$$

where D_i records decision authority and reasons for suspension, A_i the available review and alternative routes, C_i their time and resource costs, P_i the eligibility or support consequences of exercising them, and O_i the opportunities that may expire during waiting. These components are not a scalar freedom score. They describe candidate inputs to Equation (5.2), not a computed guarantee or an equilibrium solution.

Two services can have equal expenditure, observed delivery time, and completion while differing in their recipients' effective scope for contestation. Whether this difference is acceptable is a normative judgment, not established by a completion-rate comparison. Separately, the empirical candidate is that effective access to reassessment or alternatives explains some protection non-arrival and opportunity loss not explained by baseline timing and resources alone. Realized waiting time may itself be changed by contestation: conditioning on it after intervention would change the estimand and can introduce selection. Matched realized summaries are useful descriptive witnesses, not causal adjustment variables.

Hypothesis 8.1 (Waiting contestability: separate prospective candidate)**.** Under a declared resource envelope and pre-intervention classification of correctable obstacles, an exercisable route for reassessment or substitution can improve on-time service relative to merely announcing that route. Test the target outcome separately from costs, other recipients' services, continuation, and unresolved cases. No universal dominance is predicted: access costs, incorrect information, review delay, safety requirements, and capacity competition can eliminate or reverse the gain. The decision rule, obstacle class, contrasts, and failure criteria must be fixed before new outcomes.

The finite study reported in Section 11.4 examines whether a restricted input record hides these distinctions, not whether this empirical candidate is true. Its package does not preserve all previously affordable routes, so it cannot identify the effect of adding rights alone. In particular, continuing to wait because deviation would forfeit support is not by itself a Nash's Cage finding. The strategies and payoffs of relevant actors, best-response stability, and collective degradation would also have to be established. No such equilibrium analysis is supplied here.

9 Observation Architecture and Ecological Sensing

9.1 A dashboard of non-fungible signals

A practical KPI vector should contain physically and institutionally distinct signals rather than one composite score:

$$\boldsymbol{k}_t = \left(K_t^E, K_t^{\text{tail}}, K_t^{\text{infra}}, K_t^{\text{prod/finance}}, K_t^{\text{bio}}, K_t^J, K_t^{\text{capture}}, K_t^\tau\right). \tag{9.1}$$

Representative components are real emissions and budget consumption; threshold exceedance frequency; infrastructure failure duration; fossil-production and financial-backflow gaps; ecosystem integrity; justice burden; detected capture; and response delay. The dashboard is not aggregated when aggregation would allow one improvement to compensate for an irreplaceable loss.

9.2 Soundscape as one ensemble sensor

Soundscape ecology distinguishes biophony, geophony, and anthrophony and provides a scalable method for observing ecological change (Pijanowski et al., 2011). The Acoustic Complexity Index (ACI) measures temporal changes in intensity within frequency bins (Pieretti et al., 2011). A schematic form is

$$\mathrm{ACI} = \sum_f \frac{\sum_t |I_{f,t+1} - I_{f,t}|}{\sum_t I_{f,t} + \epsilon}. \tag{9.2}$$

The Normalized Difference Soundscape Index (NDSI) contrasts selected biophony and anthrophony bands:

$$\mathrm{NDSI} = \frac{B - A}{B + A + \epsilon}. \tag{9.3}$$

Automated soundscape analysis has been used to track faunal recovery across tropical forest restoration gradients (Müller et al., 2023). However, meta-analysis shows that acoustic indices are context-dependent proxies rather than universal measures of biodiversity (Alcocer et al., 2022). Therefore

$$\widehat{B}_t = \mathcal{F}_{\mathrm{eco}}\left(\text{soundscape, eDNA, remote sensing, field survey, camera traps, local knowledge}\right), \tag{9.4}$$

with uncertainty $\sigma_{B,t}$ and site-specific validation. The trigger should use posterior degradation probability, not raw loudness:

$$\mathbb{P}(B_t < B_{\mathrm{baseline}} - \delta \mid \boldsymbol{y}_{0:t}) > p_{\mathrm{crit}} \Longrightarrow \text{review or response}. \tag{9.5}$$

Randomized sensor placement, hidden audit sensors, continuous sampling, playback anomaly detection, and protected access for sensitive species locations are part of the measurement design.

10 Red-Team: How the New OS Will Be Gamed

A governance model that assumes compliance after adoption is incomplete. Regulated actors adapt. Let the attack policy be

$$\boldsymbol{\pi}_i^{\mathrm{hack}} \in \arg\max_{m_i} \left[B_i^{\mathrm{rent}} + B_i^{\mathrm{delay}} + B_i^{\mathrm{legitimacy}} + B_i^{\mathrm{access}} - C_i^{\mathrm{penalty}} - C_i^{\mathrm{audit}} - C_i^{\mathrm{legal}} \right]. \tag{10.1}$$

The target is often not physical improvement but maximal legal score at minimal transformation cost.

Table 4: Representative attack–defense pairs.

Attack surface	Realistic adaptation	Defense
Boundary laundering	Outsource or sell high-emission assets; reduce territorial or Scope 1 emissions while value-chain or consumption emissions rise.	Combine organizational, product, facility, consumption, and ownership accounting; retain transition responsibility after divestment for a defined period.
Offset substitution	Purchase low-cost credits and present finance as direct abatement.	Separate reduction, removal, and contribution claims; restrict credits to verified residual emissions; impose additionality, durability, and double-counting liability.
KPI cherry-picking	Improve carbon intensity while absolute emissions rise; emphasize renewable investment while fossil production expands.	Use mandatory KPI bundles, hard non-fungible floors, fixed core metrics plus rotating audit metrics, and absolute as well as intensity measures.
Financial instrument gaming	Select easy sustainability targets, weak coupon penalties, or redemption before assessment.	Require material penalties, no early escape before target dates, independent baselines, absolute outcome metrics, and consequences beyond coupon adjustment.

Attack surface	Realistic adaptation	Defense
Trade circumvention	Re-route goods, alter product classification, split shipments, or supply low-emission lots only to regulated markets.	Facility-level product passports, beneficial-ownership tracking, anti-circumvention rules, and conservative default factors when traceability is absent.
Soundscape theatre	Place sensors in favorable patches, shift disturbance outside sampling windows, or play recorded biophony.	Stratified randomized placement, continuous and surprise sampling, cross-sensor fusion, playback anomaly detection, and ecological composition metrics.
Adaptation substitution	Claim adaptation expenditure while mitigation declines or carbon lock-in grows.	Score adaptation net of induced emissions, lock-in, burden transfer, and maladaptation; do not allow adaptation to offset mitigation backsliding.
Justice backlash engineering	Concentrate transition costs on low-income households or dependent regions, then mobilize resulting opposition.	Couple every price or supply trigger to dividends, affordability floors, worker protection, regional investment, participation, and loss-and-damage finance.
Legal delay	Use review, litigation, transition periods, and exceptions to postpone enforcement while rents continue.	Automatic default rules, expiry, escrowed liabilities, time-limited appeals, and explicit delay costs.
Narrative capture	Reframe "transition" as indefinite preparation; use future technology promises to justify present expansion.	Evidence-backed claim standards, boundary disclosure, delivered-outcome accounting, legal liability, and zero credit for undelivered removals.
Data flooding	Publish voluminous, incomparable reports that increase audit cost and hide material information.	Machine-readable minimum schemas, open metadata, facility-level data, independent assurance, auditor rotation, and public replication.
Emergency-power capture	Use safety triggers to centralize authority indefinitely or suppress contestation.	Predefined release rules, judicial review, sunset clauses, rights floors, transparent models, and compensation for erroneous triggers.

The attack catalogue implies six general defenses:

$$\mathsf{AntiCapture} = \mathsf{Triangulation} + \mathsf{Automation} + \mathsf{Liability} + \mathsf{AntiDelay} + \mathsf{Justice} + \mathsf{AdversarialAudit}. \quad (10.2)$$

The effective capture term may be represented as

$$c_t^{\mathrm{eff}} = \frac{c_t^{\mathrm{attempted}}}{1 + \mathsf{AntiCapture}_t + R_t^J + \mathsf{LegalExposure}_t}. \quad (10.3)$$

This expression is schematic; its empirical content would require domain-specific estimation.

11 Empirical Anchors and Claim Boundaries

Table 5: Selected empirical anchors. They motivate variables and failure modes but do not validate the full model.

Observation	Evidence	Model relevance
Non-punitive Paris compliance architecture	Article 15 and the PAICC specify a facilitative, non-adversarial, non-punitive mechanism (United Nations Framework Convention on Climate Change, 2015; United Nations Framework Convention on Climate Change, 2026).	Illustrates weak direct penalty coupling; does not imply that transparency and facilitation have zero value.
Persistent policy-temperature gap	UNEP 2025 estimated 2.3–2.5 °C under full NDC implementation and 2.8 °C under current policy (United Nations Environment Programme, 2025).	Motivates separating commitments from physical trajectory.
Fossil-production inconsistency	Governments collectively planned more than twice the 2030 production consistent with a 1.5 °C pathway (Stockholm Environment Institute et al., 2025).	Motivates a supply-side state and production-gap trigger.
Record atmospheric concentrations	WMO reported 423.9 ppm globally averaged CO_2 in 2024 (World Meteorological Organization, 2025).	Anchors the physical state variable; concentration is not a complete welfare metric.
Multiple Earth-system boundaries	Recent boundary assessments integrate climate, biosphere, water, nutrients, and justice (Rockström et al., 2023; Richardson et al., 2023).	Supports coupled constraints rather than a single temperature KPI.
Context-sensitive acoustic indicators	Soundscape monitoring can track ecological recovery, while acoustic indices have limited universal proxy validity (Müller et al., 2023; Alcocer et al., 2022).	Supports ensemble sensing and explicit uncertainty rather than a single acoustic score.

11.1 What prior interventions support, and what they do not

Faster public procurement payment can relieve firms' financing constraints, but the Quickpay study also reports displacement of employment at other firms, with near-zero net employment gains in tight local labor markets (Barrot and Nanda, 2020). The relevant evaluation boundary therefore includes users of shared resources outside the treated group. In Kenya, changing the timing of insurance payments substantially increased take-up (Casaburi and Willis, 2018); the contract terms and multiple mechanisms prevent treating this as a pure equal-cost liquidity experiment, and enrollment is not eventual contractual performance. Supply-network evidence on specific inputs supplies a different warning: funds do not automatically create substitutable physical capacity (Barrot and Sauvagnat, 2016).

Existing protection can work. Disaster-related public transfers extend beyond dedicated disaster aid (Deryugina, 2017). Research on Katrina victims finds income recovery alongside persistent relocation (Deryugina et al., 2018); one cannot assume monotonic collapse of every capacity after a disaster. Conversely, long-run mortality estimates for tropical cyclones (Young and Hsiang, 2024) cannot be canceled

by income recovery in a different population, period, and design. None of these studies identifies this project's proposed household payment-delay-to-harm mechanism.

Early-transfer evidence also requires precise comparisons. The main comparison in Pople et al. (2026) is anticipatory recipients versus non-recipients, not an equal-amount randomized comparison of early and late receipt. A separate WFP evaluation summary describes randomized equal transfers before and after flooding (World Food Programme, 2026). Our recorded reading of the latter is the publisher's overview, not its full methods and tables; no effect size or mediated liquidity share is imported. These are precedents and constraints on our design, not validations of Hypothesis 5.1.

11.2 Existing development results: failures retained

The repository's earlier lanes are different instruments, not exchangeable replications. In the synthetic feasibility baseline, irreversible entries were 98/192 for a simple threshold, 93/192 for a hysteretic threshold, and 70/192 for reserve control. Under common optimistic bias, ten paired cases favored hysteresis over reserve. Zero budget, zero capacity, and fully missing observations each failed in every evaluation episode under the declared fallback. These are model-specific failures, not proofs of universal impossibility.

The sustained-plan baseline reduced entries from 17/48 to 7/48, but the new screen kept emergency operation active for an average 66.958 of 72 steps and exhausted its budget. Finite candidate failure did not prove the absence of every feasible policy. In the synthetic heat comparison, retaining existing protection yielded lower residual exposure with information plus linkage in 26 of 72 primary conditions, higher exposure in 22, and equal exposure in 24. These are signs of condition-mean differences, not 72 independent field sites, a policy success rate, or significance tests. The study used 32 shared seeds per condition; its high-friction baseline partly encodes zero expected effectiveness. There is no aggregate winner established by these counts.

The fuel-carbon accounting lane classified 17 of 21 rows as reconciled, one as rejected, and three as unknown. It did not identify operational fuel stocks or the effect of preserving an electricity service through substitution. The heat public-record audit retained missing opportunity denominators, response clocks, and links from contracts to actual wages. Unknown is not absent protection. These results generated the present hypothesis and cannot serve as an independent confirmatory test of it. Source paths and study-specific denominators remain in the repository's dated proposal and result notes.

11.3 Frozen executability twins: completion is not the diagnostic conjunction

The separately frozen finite assay enumerated 36,864 artificial worlds and four arms (147,456 arm-worlds). Under early rather than usual payment, target completion increased in 960 worlds. Of those, 96 also retained the other opportunity, continued the target service financially, and did not increase unpaid obligations; 448 lost only the other opportunity, 96 failed continuation with increased unpaid obligations only, and 320 had both failures. These four cells partition the 960 gains. Among the 288 target gains in financially unconstrained worlds, all displaced the other opportunity. This is an internal counterexample to identifying liquidity relief from target completion alone, not an estimate of real displacement.

The denominator is a designed catalogue, not independent observations or a population distribution. The other opportunity is an additional service competing for the same payer and capacity; the baseline protected allocation is reserved in all arms. The retained independent recount checks outputs without importing the simulator, but does not independently implement the generating world. Neither this assay nor its zero-ambiguity full-input view validates real protection, consent, or contestability. The new candidate must not relabel these results as its own confirmatory evidence.

11.4 Waiting-contestability twins: a paid package, not rights alone

A second, separately frozen assay enumerated 18,432 artificial worlds across three arms (55,296 arm-worlds). *B* retains ordinary operation, including an existing review route where specified. *N* adds a label without changing information, cost, or operation; all of its trajectories equal *B* by construction, a software negative control rather than evidence about real nominal reforms. *E* adds review access, payer-funded application fees, and exemption from application-triggered eligibility suspension. Initial funds and per-period capacity are paired. The fixed decision rule uses the actor's available guidance, not the evaluator's future safety assessment.

The package pays one unit of setup cost in every world from a payer initially holding two or three units, including worlds with no usable alternative. Thus setup consumes one-half or one-third of that budget. The model does not amortize setup over many recipients or finance it externally. Application, review, service, and maintenance compete for the named payer's funds; review and delivery also compete for capacity. The ordinary delivery window is one-shot, whereas an approved alternative can retry until expiry. These are declared modeling choices, not measured institutional properties.

Table 6: Frozen $E - N$ on-time target-completion differences. Counts are over a designed finite catalogue, not population frequencies, independent samples, or causal estimates.

Target outcome	Worlds / 18,432
Increased	212
Decreased	6,370
Unchanged	11,850

Among the 212 target gains, 50 also retain the other service, sustain the target financially through follow-up, and avoid increased unpaid obligations. The remaining disjoint cells are: 56 losing only the other service; 50 with continuation failure or increased debt only; and 56 with both. These are diagnostic components, not a universal welfare or legitimacy criterion. Across the whole catalogue the other service decreases in 5,472 worlds and increases in 48. A fall in maintenance debt can simply mean that initial service never occurred and its maintenance obligation was never incurred.

The narrow `can_request` indicator means authority plus affordability of application and review, not the existence of a safe substitute or successful redress. It increases in 9,792 worlds and decreases in 576. In the implemented *E* package, fee payment is reassigned to the payer without a fallback to the previously usable self-paid application route. All 576 decreases occur where baseline review access exists. Legal permission remains, but operational access need not. Consequently this package does not satisfy the premise that all old feasible options are retained; neither its gains nor its losses identify the effect of rights alone.

One retained witness, `w00032`, makes this distinction concrete. The ordinary arm funds both services at time 2. Under *E*, setup consumes one unit even though no alternative exists and no application is made; the other service then uses the remaining unit, leaving the target unfunded. That is an unused-package resource cost, not a harm caused by exercising an appeal. The complete source, contract, traces, and fixed-order witnesses accompany the result; none was retuned after enumeration.

Observation and outcome also remain separate. The declared *consequences* view has 6,144 record classes: the difference in application affordability is constant within every class, but target-completion differences still vary within 1,242 classes containing 3,726 worlds. That view omits the alternative's existence/safety; the full-model view includes evaluator-only state. Full-input decidability is therefore a deterministic construction, not an attainable operational guarantee. Long unresolved reviews, strategic bargaining, institu-

tional rule revision, and real protection efficacy are not implemented. Same-code replay and independent event recount matched; the latter does not independently regenerate the world model.

11.5 COP31 source reading: institutional and protection clocks

As of 10 November 2026, COP31 is in its opening phase in Antalya (9–20 November), not a completed negotiation (UNFCCC, 2026). We use its institutional reporting as an observation problem, not a verdict on the conference. Existing review and delivery arrangements belong in the baseline.

The GCF report's GCF-2 figures as of 31 July give mean approval-to-first-disbursement times of 6.3 months for the simplified process and 10.1 months for the standard process, alongside 34 and 44 percent not yet disbursed, respectively (paragraph 153). The paragraph does not establish exact sample counts or an all-case unconditional mean. Its nine-month review target excludes intervening proposal-preparation time (paragraph 159, footnote 47) (Green Climate Fund, 2026). These are different clocks, not evidence that delay was transferred. First disbursement is not beneficiary service, and undisbursed need not mean failed. The report does not identify the individual consequences of challenging a condition. Project-level authority, access, eligibility, and service records would be required for that question; Equation (8.1) supplies a proposed observation contract, not an accusation against this institution.

11.6 Frozen public-data audit: the observable unit matters

An exploratory CPU audit acquired OpenFEMA and World Bank API responses on 25 October 2026 JST, before this manuscript revision. It added no policy intervention or new synthetic simulation. The frozen snapshot, contract, code, hashes, and output tables accompany the paper under `artifacts/cross_domain_audit_v01` and `experiments/cross_domain_audit_v01`.

For major disasters declared in 2000–2024, 29,471 designated-area rows reduce to 1,542 declaration identifiers. Median incident-start-to-declaration time is 40 calendar days, with quartiles 17 and 65; computing the same statistic on area rows gives 37 days. The latter reweights declarations by designated areas. The request-date denominator is 1,541 because one is missing. Negative date differences and suspicious source dates are retained, not corrected by inference. These are three administrative clocks among declared cases, not a denominator of all affected people, a payment clock, or evidence of 40 unprotected days. Existing local and permanent services may precede a federal declaration (Federal Emergency Management Agency, n.d.).

For Bangladesh and Kenya, 2000–2024 observations for two external-debt-service ratios provide 100 country–year–indicator cells without missing values. Both denominators are export receipts, not government revenue or cash. The Bangladesh change between the 2000–2004 and 2020–2024 mean ratios is +3.15 percentage points for total external debt service but -0.91 for public and publicly guaranteed service. This difference warns against an unrestricted fiscal-capacity proxy; it does not identify crowding-out of adaptation or recipient nonpayment. The two countries were selected because of the cited transfer and insurance studies, not as a representative global sample (World Bank, n.d.[b]; World Bank, n.d.[a]).

Offline replay and independent arithmetic checks establish reproducibility of these descriptions, not correctness of each administrative date or causal identification. The two datasets are not joined into a mechanism estimate. Documented source reading, synthetic development results, administrative descriptions, and future hypotheses remain separate evidence classes. RVCIM remains F0 even though the administrative records themselves are real.

The paper advances an architecture, not the following stronger claims:

- It does not prove that the Paris Agreement was intentionally designed to fail.
- It does not identify one exact global recovery boundary.

- It does not assume that every actor is selfish, identical, or perfectly rational.
- It does not imply that punishment alone is optimal, or that all cooperation should be centralized.
- It does not treat soundscape indices as a universal biodiversity truth machine.
- It does not show that an automatic controller can resolve distributive conflict without politics.

12 A Falsifiable Research Program

12.1 Minimal simulation environment

A first implementation should be an agent-based partially observable stochastic game, not a full integrated assessment model. Let actors vary in economic dependence, power, exposure, externalization capacity, horizon, trust, and capture ability. Compare at least four governance arms:

1. **Weak-coupling baseline**: observation and voluntary reporting with low $\partial \boldsymbol{\iota}/\partial \boldsymbol{k}$.
2. **Nominal trigger**: deterministic institutional response without capture defense.
3. **Robust reserve controller**: ambiguity-aware triggers using CR_t and viability constraints.
4. **Full RVCIM**: robust triggers plus justice buffers, model plurality, adversarial audit, and accountable override.

Key experimental sweeps include physical uncertainty, observation noise, common-mode model error, capture budget, policy delay, capital turnover, trust decay, and unequal transition burden. Outcomes include

$$R_{\text{irr}}(H) = \mathbb{P}(\tau^{(t)}_{\mathcal{X}_{\text{irr}}} \le H), \tag{12.1}$$

$$CR_{\min} = \min_{t \le H} CR^{\text{sys}}_t, \tag{12.2}$$

$$\mathsf{PG}_{\text{cum}} = \sum_{t \le H} \mathsf{PG}_t, \tag{12.3}$$

$$\mathsf{CA} = 1 - \frac{\|\boldsymbol{c}^{\text{eff}}\|}{\|\boldsymbol{c}^{\text{attempted}}\| + \epsilon}, \tag{12.4}$$

$$\mathsf{JS} = R^J_t - \mathsf{BacklashRisk}_t. \tag{12.5}$$

False-positive and false-negative trigger rates must both be measured. For irreversible risks, a false negative may have much greater cost, but excessive false positives can destroy legitimacy and thus future control capacity.

12.2 Hypotheses

Hypothesis 12.1 (Coupling)**.** Holding physical dynamics, actor preferences, and capture fixed, increasing the credible KPI-to-payoff coupling Λ_i for decisive actors reduces defective action relative to a monitoring-only baseline.

Hypothesis 12.2 (Capture decay)**.** A nominal trigger initially improves outcomes but its effect decays under repeated strategic adaptation when capture is unmodeled; adversarial audit and function separation reduce that decay.

Hypothesis 12.3 (Reserve advantage)**.** Under delayed and uncertain tipping dynamics, reserve-based triggers reduce entry into $\mathcal{X}_{\text{irr}}$ relative to damage-threshold triggers, at the cost of a higher false-positive

rate.

Hypothesis 12.4 (Justice durability)**.** Transition policies with automatic justice buffers produce lower backlash, higher coordination reserve, and greater long-run policy persistence than otherwise identical punitive policies.

Hypothesis 12.5 (Sensor ensemble)**.** A multimodal ecological observation ensemble is more robust to manipulation and domain shift than a single KPI, but remains vulnerable to common-mode model error.

Hypothesis 12.6 (Adaptive path value)**.** Policies with staged commitments, signposts, and reversible early actions retain more option value under deep uncertainty than fixed long-horizon plans with equivalent expected benefits.

12.3 Stress tests

At minimum, evaluate scenarios in which: the boundary is 30% closer than the median model; no reliable early warning appears; all models share a common bias; KPI data are accurate but institutions fail to act; institutions act but backlash forces repeal; an industry coordinates manipulation; two physical thresholds cascade; and emergency powers are captured. A design that succeeds only when all actors report honestly and all models are well calibrated is not an anti-capture architecture.

12.4 After the finite assay: distinguish additions from replacements

The timing and contestability candidates in Hypotheses 5.1 and 8.1 remain empirical questions. The frozen assays in Sections 11.3 and 11.4 retain their negative outcomes and only characterize their declared finite contracts. In particular, a package that replaces a payment route and consumes substantial setup resources is not a clean test of adding an otherwise unchanged option.

The next design question is whether a claimed option expansion actually preserves the previously feasible protection routes, and at whose expense. A cost-sharing scheme, retention of the self-paid fallback, and separate changes to authority, application support, or eligibility would require distinct contrasts. The elementary set-inclusion comparison in Section 5 applies only under its stated premises; this is not a new monotonicity theorem or a requirement that all redistribution leave every actor costless. Where an old route is intentionally displaced, record the loss and its justification rather than describe the intervention as a pure addition.

No replacement experiment is supplied or run here. A subsequent study must declare its resource envelope, setup-cost allocation unit, component contrasts, information schedule, shared-capacity rule, old-route fallback, observation maps, and decision policy before new outcomes. Any revised catalogue needs a new registration and output directory, retaining the present failed and null cases rather than tuning them away. Evaluating only cases with realized short waits or successful applications would change the target of comparison and select on outcomes.

A later field design needs independent evidence on legal and practical access and separate authorization. It cannot withhold necessary protection, remove existing appeal rights, or delay rescue to create a control. A finite witness is an input-contract warning, not a diagnosis of a real claimant, institution, or equilibrium.

13 Executable Reference and Feasibility Contract

The repository companion turns the minimal research program into a small, inspectable experiment. Its purpose is to establish that the paper's formal pieces can be composed into one deterministic software loop and subjected to failure tests. Execution is an audit surface, not an evidentiary shortcut.

13.1 Feasibility ladder and admissible claims

The distinction between implementation and validation is organized as a four-level ladder. Progress at one level does not silently confer the claims of the next.

Table 7: Feasibility ladder for the manuscript and companion implementation.

Level	Object	Admissible claim	Additional evidence required to advance
F0	Executable structural toy	The declared mechanisms compose into a coherent, inspectable, replayable loop under recorded conditions.	Deterministic tests, explicit assumptions, traceable outputs, hash-addressed receipts, and a reviewed external anchor for authenticity claims; the same-tree manifest checks internal consistency only.
F1	Stylized calibrated model	A narrow mechanism reproduces selected regularities under documented assumptions.	Parameter provenance, identification argument, alternative mechanisms, sensitivity analysis, and held-out tests.
F2	Sectoral or jurisdictional shadow model	The system may support bounded, non-actuating analysis in a declared domain.	Scoped legal authority, live-data validation, distribution-shift monitoring, independent review, and prospective evaluation.
F3	Reversible institutional pilot	A specific mechanism is operationally feasible under declared safeguards.	Rights floor, appeal, compensation, rollback and release rules, accountable ownership, and measured real-world outcomes.

This release is F0. A successful run, an ordered comparison table, or a lower toy irreversible-entry rate cannot be promoted into a climate forecast, a causal policy estimate, or evidence that an institutional design is legitimate.

The current manifest and receipt system detects missing or byte-modified declared files relative to metadata committed in the same tree. It is not a signature, transparency-log inclusion proof, independent build receipt, or proof that the prose attached to a hash is historically true. Provenance statements in this release are therefore operator-attested except where repository history supplies an independent earlier anchor.

13.2 Paper-to-code correspondence

Table 8 makes the correspondence explicit enough to audit, while also stating where the implementation compresses the formal object.

Table 8: Correspondence between formal objects and the reference implementation.

Paper object	Implementation surface	F0 interpretation
x_t, s_t	`WorldState`	Normalized physical pressure, biosphere, institution, trust, justice, policy, support, and audit state.
$a_{i,t}, \Delta_i$	`actor_actions()`	Heterogeneous payoff-sensitive cooperation, defection, capture, restoration, and symbolic action.
y_t, k_t	`observe_pressure()`	Noisy observation with manipulation and audit correction.
Θ_t	`Environment.model_boundaries`	A finite model ensemble with common-mode bias and structural allowance.
CR_t, ρ_t	`estimate_reserve()`	Conservative estimated exit time minus endogenous response time.
Γ	`select_mode()`, `schedule_policy()`, `advance_policy()`	Requested trigger mode, pending transition and delay, eventual active mode, and release logic. The trace exposes `requested_mode`, `active_mode`, `pending_mode`, their names, and `pending_delay` separately.
c_t^{eff}	`effective_capture_value()`	Attempted capture after audit, function separation, justice, and policy exposure.
PG_t	Trace and episode accumulators	Symbolic action minus scaled verified physical improvement.

The preserved v0.2 code compares weak coupling, nominal trigger, robust reserve, and full RVCIM. Within an episode, arms receive paired environmental draws. Pairing does not equalize all capabilities, and evaluator-only state enters part of this original loop. It is therefore a structural reference, not a clean causal comparison of trigger designs. The separate feasibility and sustained-response lanes narrow those issues under their own contracts. Neither they nor the original code implement the full pathway set in Equation (5.2) or the revisability proposal in Section 8.

13.3 Reference implementation contract

The executable contract is intentionally narrow and fail-closed:

1. **Runtime.** The simulator uses Python 3.10 or newer and only the standard library. The checked-in source is the readable source of truth; execution does not depend on hidden payload assembly.

2. **Declared input.** A run resolves `simulation/configs/minimal.json`, selected arms, episode count, seed, and command-line overrides into `resolved_config.json`. Unknown configuration keys are rejected.

3. **Paired randomness.** The episode seed determines one common environment for all selected arms. Arm ordering cannot change the sampled exogenous episode.

4. **Observable outputs.** Every complete run writes `summary.csv`, `episodes.csv`, `trace.csv`, `comparison.md`, `resolved_config.json`, and `receipt.json`. The receipt records the claim boundary, command, declared environment, source identity, configuration identity, and output hashes. The trace records requested, pending, and active modes in distinct columns. A request may remain pending while the active mode and its policy targets are delayed.

5. **Verification.** Receipt verification resolves recorded paths relative to the receipt, recomputes SHA-256

identities, and returns non-zero for a missing or modified file. Repository verification also checks same-tree manifest consistency and the committed reference receipt, then replays the declared reference command and byte-compares its deterministic outputs. Successful replay establishes byte consistency under the exercised source and configuration; it does not establish semantic correctness, historical provenance, or authenticity.

6. **Failure visibility.** False-positive and false-negative requested-trigger classifications are reported together. `emergency_request_rate` counts steps on which the trigger requests emergency-or-higher mode; it does not measure time spent in an active emergency mode. Skipped executable tests, absent release artifacts, and hash mismatches are failures, not successful partial results. Manuscript buildability is qualified separately with an explicit TeX toolchain and must not be inferred from Python CI.

The reference command is:

```
python3 -m simulation run \
  --config simulation/configs/minimal.json \
  --episodes 64 --seed 7 \
  --out artifacts/reference_run --overwrite

python3 -m simulation verify \
  --receipt artifacts/reference_run/receipt.json
```

Claim boundary

What F0 does not establish. The normalized parameters are selected to expose an inspectable mechanism gradient. They do not estimate climate sensitivity, tipping distributions, institutional response, actor preferences, or real intervention effects. The executable establishes correspondence, byte replayability under the recorded source, configuration, seed, and compatible runtime, and falsifiable interfaces—not the correctness of mode semantics, historical provenance, authenticity, empirical truth, policy rank, safety, legality, or democratic legitimacy.

14 Limitations and Open Problems

First, the cooperative/defective partition is partly normative. An action can reduce emissions while violating justice or biodiversity constraints. The paper therefore requires plural hard constraints rather than a single climate score, but disagreements over those constraints remain political.

Second, robust worst-case methods can become excessively conservative. Ambiguity sets may contain implausible models, and powerful actors may weaponize uncertainty to block beneficial transformation. The response is not to ignore uncertainty but to combine hard safety constraints with safe learning, staged trials, explicit information value, and periodic model-set revision.

Third, institutional actuators do not behave like physical actuators. Enforcement depends on legitimacy, legal authority, implementation capacity, and interpretation. Equations such as Equations (3.12) and (7.6) are formal abstractions that must be instantiated separately in each jurisdiction.

Fourth, automatic triggers create constitutional risk. Rules justified by an unknown boundary can be used to normalize emergency powers. Release conditions, rights floors, transparent models, independent appeal, compensation, and legislative renewal are therefore part of the controller, not optional safeguards.

Fifth, the robust viability kernel may be computationally intractable in high-dimensional coupled systems. Approximations, surrogate models, scenario discovery, and decomposition will be necessary. Model

plurality can reduce single-model dependence but does not eliminate correlated error.

Sixth, physical stabilization after payoff inversion may be slow. A governance reform can be successful in strategic terms while concentrations, ice loss, or ecological damage continue due to lag. Evaluation must distinguish policy coupling, action change, and delayed physical response.

Seventh, the pathway contract may itself be costly, selective, or captured. Accepted applications alone cannot identify unmet need; full-population needs and counterfactual commitments may remain unobserved. A richer ledger can increase burden without improving protection. Its incremental value must be compared with simpler existing practice, and its own boundaries must be open to correction.

The waiting assay adds further limits: its large per-case setup charge, substituted fee payer, fixed non-anticipating heuristic, and asymmetric delivery windows define a particular package. It is neither a pure rights expansion nor a calibrated institutional comparison. Its affordability indicator is narrower than effective contestability, and its existing-protection floor is assumed rather than empirically established.

Finally, the literature synthesis is selective and includes abstract-level readings explicitly marked in the source ledger. The new hypotheses arose after seeing development outcomes. The public-data audits do not identify their causal mechanisms, and no complete institutional or Earth-system digital twin has been calibrated. This paper has not demonstrated empirical superiority or established the academic novelty of its integration.

15 Conclusion

Nash's Cage names a system in which local rationality, physical externalization, short horizons, partial observation, and institutional capture jointly stabilize collective degradation. The architecture is dangerous not only because the physical state worsens, but because it can shrink the future set of feasible recoveries. The decisive threshold may therefore precede visible collapse: remaining safe time becomes shorter than institutional and biophysical braking time.

RVCIMresponds by changing the order of operations. It does not maximize short-term welfare and then price the damage. It first constrains irreversible risk and injustice, then optimizes within the remaining viable region. It does not assume that a better dashboard is governance. It measures the full chain from observation to actuator, payoff, behavior, and physical response. It does not assume reform survives contact with regulated actors. Capture is a strategic state variable, and anti-capture design is an institutional immune system.

The manuscript's core proposition is deliberately conservative:

Core claim

When the irreversible boundary is unknown, governance should preserve the ability to brake rather than infer safety from the absence of visible collapse.

The next question is consequently more specific than whether a dashboard improves or an emergency order fires. Who may prolong a wait, who can change its conditions, and what does a recipient lose by seeking another route? Financing a wait and having an effective choice about it are different dimensions; their normative significance and empirical effects must not be collapsed. Which protection pathways are actually available before their deadlines, who can carry the intermediate burdens, what is displaced, and can mistakes and exclusions be corrected? Observation may matter through several channels; favorable incentives still require executable action; the end of an emergency does not erase its losses or continuing obligations. The implemented waiting package did fail to improve target completion in many declared worlds, and its few target gains did not generally preserve other services and continuation. This does not

settle the value of contestation: it exposes a distinction between a legal permission, an affordable application, and a protection pathway that survives its own implementation costs. The contribution includes failures, existing institutional successes, and unresolved mechanisms.

A Repository Evidence Map

The companion repository is https://github.com/RyoSpiralArchitect/Nash-s_Cage. Use the Git revision distributed with this PDF, rather than assuming that the moving default branch contains identical material. The manuscript revision does not alter the following frozen results. The research index records source versions and actual reading scope.

- Research index and prior work: `docs/research/README.ja.md` and `docs/research/prior-work/README.ja.md`.
- Theory and original result denominators: `docs/proposals/2026-10-24-joint-executability/PROPOSAL.ja.md`, with its companion `SOURCES.ja.md`.
- Synthetic result records: `docs/FEASIBILITY_V03_RESULTS.ja.md`, `docs/SUSTAINED_V04_RESULTS.ja.md`, and `docs/HEAT_INSTITUTION_V01_RESULTS.ja.md`.
- Accounting and public-audit boundaries: `docs/POWER_ACCOUNTING_RESULTS.ja.md` and `experiments/heat_public_audit_v01/CONTRACT.ja.md`.
- Cross-domain interpretation and reproduction: `docs/research/2026-10-25-cross-domain-executability/ANALYSIS.ja.md` and its `REPRODUCIBILITY.ja.md`.
- Frozen administrative summaries and receipts: `artifacts/cross_domain_audit_v01/analysis_20261025/summary.json`; source queries and hashes: `artifacts/cross_domain_audit_v01/snapshot_20261025/manifest.json`.
- Frozen executability results and independent recount: `docs/research/2026-11-04-executability-twins/`; source contract: `experiments/executability_twins_v01/`.
- COP31 source ledger and GCF clock analysis: `docs/research/2026-11-10-cop31-executability/`.
- Waiting-contestability results and recount: `docs/research/2026-11-10-waiting-contestability/`; frozen source: `experiments/waiting_contestability_twins_v01/`; full outputs: `artifacts/waiting_contestability_twins_v01/enumeration_20261110/`.
- This revision and review record: `docs/research/2026-11-10-manuscript-v05/`. The preceding, unexecuted-at-publication design remains at `docs/research/2026-11-10-manuscript-v04/`; earlier build records remain unchanged.

B Notation Summary

Symbol	Meaning
$\boldsymbol{x}_t$	Full physical, agent, institutional, and narrative state.
$\boldsymbol{s}_t$	Physical and ecological state.
$\boldsymbol{a}_{i,t}$	Actor i's emissions, fossil, decarbonization, symbolic, capture, restoration, and adaptation actions.
$\boldsymbol{\iota}_t$	Institutional actuators and capacities.

$\boldsymbol{n}_t$	Narrative, awareness, trust, and legitimacy state.
$\boldsymbol{y}_t$	Raw multimodal observations.
$\boldsymbol{k}_t$	Institutional KPI and reserve dashboard.
$\boldsymbol{c}_t$	Capture vector attacking metrics, institutions, delay, narrative, justice, and finance.
Θ_t	Ambiguity set of plausible system models.
$\mathcal{X}_{\text{safe}}$	Present-time safe and just constraint set.
$\mathcal{V}_t^{\text{rob}}$	Robust viability set under feasible common policies.
$\mathcal{X}_{\text{irr}}$	Functionally irreversible state set.
$\tau_{\mathcal{A}}^{(t)}$	First-passage delay from decision time t into set $\mathcal{A}$.
$\rho_t(H)$	Robust recoverability over horizon H.
CR_t	Remaining lower-bound exit time minus upper-bound response time.
Δ_i	Cooperation payoff minus defection payoff.
Λ_i	KPI-to-payoff coupling strength.
PG_t	Symbolic action minus scaled verified physical improvement.
R_t^J	Justice and legitimacy reserve.
$\mathsf{OWD}(a)$	One-Way Door index for action a.
$\ell_i(s;\pi,m,\theta)$	Actor-specific financial slack above a declared protected minimum.
$\mathcal{E}_m^H(t)$	Conceptual non-anticipating, deadline-constrained joint execution set.

C Minimal Control Loop

```
At each decision time t:

1. Observe:
   y_t <- independent multi-sensor observations

2. Update uncertainty:
   Theta_t <- update plausible models + structural-error allowance

3. Estimate state and reserves:
   k_t, V_rob_t, rho_t, CR_t <- robust inference(y_0:t, Theta_t)

4. Red-team the observation:
   k_robust <- sensor fusion - manipulation allowance + audit correction

5. Select requested mode:
   if rho_t < rho_min:
      requested_mode <- loss minimization
   else if lower_bound(CR_t) <= 0:
      requested_mode <- emergency braking
   else if CR_t is low or boundary uncertainty is high:
      requested_mode <- precaution
   else:
      requested_mode <- adaptive normal

6. Select policy:
   maximize durable welfare + information value + option value
   subject to:
      irreversible-risk <= epsilon
      justice reserve >= J_min
      prohibited non-fungible loss == 0
```

```
7. Schedule and advance actuators:
   pending_mode, pending_delay <- schedule(requested_mode)
   active_mode <- advance pending transition when its delay elapses
   apply price, cap, permit, finance, restoration, dividend, compensation
   according to active_mode

8. Audit adaptation:
   search for metric, boundary, delay, narrative, finance, and justice hacks

9. Publish:
   observations, models, uncertainty, requested/pending/active mode,
   burdens, beneficiaries, override and release conditions

10. Require review_interval < controllability_reserve; otherwise increase review cadence.
```

D Cage-Inversion Constitutional Invariants

1. **Unknown is not zero.** Missing evidence is not a safety certificate.
2. **No silent loss of controllability.** Reserve deterioration must itself be a trigger.
3. **No compensation across irreplaceable boundaries.** Non-fungible losses cannot be converted into generic credits.
4. **One-way actions carry the proof burden.** Irreversibility raises the required confidence of safety.
5. **Delay has a price.** Appeal and review cannot be costless defection strategies.
6. **Justice is a floor.** Aggregate benefit cannot erase intolerable burden concentration.
7. **No single epistemic controller.** Measurement, modeling, triggering, auditing, and appeal are separated.
8. **Override is temporary and expensive.** Exceptions require public reasons, expiry, review, compensation, and traceability.
9. **Every emergency trigger has a release rule.** Safety governance cannot become an unbounded permanent exception.
